## 1. INTRODUCTION

In the big-data deluge era, the canonical matrix and tensor paradigm over an algebraically closed field plays an essential role in many areas, including but not limited to machine learning, computer vision, pattern analysis, and statistic inference. Under the canonical matrix and tensor paradigm, observed data are given in the form of high-order arrays of canonical scalars (i.e., real or complex numbers). For example, an RGB image is a real number array of order three, two orders for the image's spatial measures, and a third for the image's spectral measures. An RGB image is also said to have three modes or three-way. A color video sequence of images is of order four, with three orders for spatial-spectral measures and the fourth-order chronological tempo.

Therefore, it is a natural question of whether there exists an extension of the field  $\mathbb{C}$  over which a generalized matrix and tensor paradigm can be established and backward-compatible to the canonical paradigm over a field. Fortunately, the answer is yes, but one had to sacrifice at least one of the axioms of a field to obtain something extended.

Among these efforts trying to generalizing the field of complex numbers, well-known is Hamilton's  $\mathbb{H}$  of quaternions, which, up to isomorphism, is a real division subalgebra

of the matrix algebra  $M_2(\mathbb{C})$  [Ham48, Roz88, HN11]. However, the multiplication of quaternions is not commutative.

Most hypercomplex number systems, including Hamilton's quaternions, are all sub-algebras of Clifford algebra, and the fruits of generating complex numbers to obtain something extended. However, Clifford algebra's hypercomplex number systems are not suitable for general data analytics partially because they are either non-commutative or incompatible with many canonical notions such as euclidean norms. These hypercomplex number systems so far only find narrow niches in geometry and geometry-related branches of physics and computer sciences [Hes03, AS<sup>+</sup>04].

## 2. FUNCTIONS FOR T-SCALARS

A matrix over  $C$  is called a tmatrix. In this article, its canonical counterpart over complex numbers is called a “canonical matrix,” or just a “matrix.”

The matrix paradigm over t-algebra  $C$  generalizes many notions of canonical matrices over complex numbers. In the following, we show how to use these t-matrix generalizations with the their MATLAB implementations.

**2.1. T-SCALAR PRODUCT:** `tproduct`. The following function `tproduct` computes the t-scalar product of two t-scalars `tscalar01` and `tscalar02`.

The multi-way circular convolution can compute the product of two scalars in the spatial domain.

More specifically, let  $C$  be the set of all  $I_1 \times \cdots \times I_N$  complex arrays, namely  $C \equiv \mathbb{C}^{I_1 \times \cdots \times I_N}$ . For all  $A_T, B_T \in C \equiv \mathbb{C}^{I_1 \times \cdots \times I_N}$ , the t-scalar multiplication  $C_T \doteq A_T \circ B_T$  is defined by the  $N$ -way circular convolution of  $A_T$  and  $B_T$  as follows.

**Definition 2.1** (T-scalar multiplication (i.e.,  $N$ -way circular convolution)). [LM20a] The  $(i_1, \dots, i_N)$ -th complex entry  $(C_T)_{i_1, \dots, i_N}$  of  $C_T \in C \equiv \mathbb{C}^{I_1 \times \cdots \times I_N}$  is given by

$$(C_T)_{i_1, \dots, i_N} \doteq \sum_{(m_1, \dots, m_N) \in [I_1] \times \cdots \times [I_N]} (A_T)_{m_1, \dots, m_N} \cdot (B_T)_{m'_1, \dots, m'_N} \in \mathbb{C} \quad (2.1)$$

$$\forall (i_1, \dots, i_N) \in [I_1] \times \cdots \times [I_N].$$

where  $m'_n = \text{mod}(i_n - m_n, I - n) + 1$  for all  $n \in [N]$ .

The t-scalar product (i.e.,  $N$ -way circular convolution) can be equivalently obtained in the Fourier domain by the Hadamard product. The computation in the Fourier domain is more efficient and is adopted in the following function `tproduct`.

**FUNCTION 1. `tproduct.m`:** t-scalar product of two scalars

```
1 function result = tproduct(tscalar01, tscalar02)
2 %This function computes the product of two t-scalars
```

```

3  assert(isequal(size(tscalar01), size(tscalar02)));
4
5  %T-scalar product computed in the fourier domain by the Hadamard
6  %product
7  result = ifftn(fftn(tscalar01) .* fftn(tscalar02));
8  end

```

The input arguments `tscalar01` and `tscalar02` are complex arrays of the same shape. The line confirms their shapes (i.e., “size” by the MATLAB colloquialism) are identical.

In line 4, multi-way Fourier transform `fftn` and its inverse transform `ifftn` are invoked. The multi-way Fourier transform and its inverse transform can be equivalently computed by MATLAB’s single-way Fourier transform `fft` and is demonstrated as follows.

FUNCTION 2. Demo: multi-way Fourier transform `fftn` implemented by single-way Fourier transforms `fft`

```

1  function fourier_transformed_tscalar = fftn(tscalar)
2      assert(isnumeric(tscalar));
3      number_of_index_axes = ndims(tscalar);
4      %Compute single-way fourier transform along each index axis.
5      fourier_transformed_tscalar = tscalar;
6      for i = 1: number_of_index_axes
7          fourier_transformed_tscalar = fft(fourier_transformed_tscalar, [], i);
8      end
9  end

```

Similarly, the multi-way inverse transform `ifftn` is computed by single-way inverse transforms `ifft` along different axes as follows.

FUNCTION 3. Demo: multi-way inverse Fourier transform `ifftn` implemented by single-way Fourier transforms `ifft`

```

1  function tscalar = ifftn(fourier_transformed_tscalar)
2      assert(isnumeric(fourier_transformed_tscalar));
3      number_of_index_axes = ndims(fourier_transformed_tscalar);
4      %Compute single-way inverse fourier transform along each index axis.
5      tscalar = fourier_transformed_tscalar;
6      for i = 1: number_of_index_axes
7          tscalar = ifft(tscalar, [], i);
8      end
9  end

```

SYNTAX

```
C = tproduct(A, B)
```

### DESCRIPTION

Output  $C$  is the multi-way circular convolution of two arrays  $A$  and  $B$ . Output  $C$  and inputs  $A$  and  $B$  are numeric arrays of the same size. This function generalizes the canonical multiplication of two complex numbers.

### EXAMPLES

Compute the multiplication of two t-scalars  $A$  and  $B$  as follows.

```
>> A = ones(3)
A =
    1    1    1
    1    1    1
    1    1    1
```

```
>> B = 2 * ones(3)
B =
    2    2    2
    2    2    2
    2    2    2
```

```
>> tproduct(A, B)
ans =
    18    18    18
    18    18    18
    18    18    18
```

Compute the multiplication of two random t-scalars  $A$  and  $B$ , both of them in the form of a  $3 \times 3$  real array.

```
>> A = rand(3)
A =
    0.4984    0.5853    0.2551
    0.9597    0.2238    0.5060
    0.3404    0.7513    0.6991
```

```
>> B = rand(3)
B =
    0.8909    0.1386    0.8407
    0.9593    0.1493    0.2543
```

```
0.5472    0.2575    0.8143
```

```
>> C = tproduct(A, B)
```

```
C =
```

```
2.4311    2.5358    2.7127
2.7564    2.5265    2.6006
2.8999    2.4472    2.4721
```

Compute the multiplication of two random t-scalars  $A$  and  $B$ , both of them in the form of a  $2 \times 3$  complex array.

```
>> A = randn(2, 3) + i * randn(2, 3)
```

```
A =
```

```
0.5377 - 0.4336i  -2.2588 + 3.5784i   0.3188 - 1.3499i
1.8339 + 0.3426i   0.8622 + 2.7694i  -1.3077 + 3.0349i
```

```
>> B = randn(2, 3) + i * randn(2, 3)
```

```
B =
```

```
0.7254 + 1.4090i   0.7147 + 0.6715i  -0.1241 + 0.7172i
-0.0631 + 1.4172i  -0.2050 - 1.2075i   1.4897 + 1.6302i
```

```
>> C = tproduct(A, B)
```

```
C =
```

```
-0.0499 + 6.6934i -15.9137 + 1.0122i  -0.5178 + 0.7970i
-14.5318 + 6.7276i  -7.0977 - 2.0930i   1.2429 + 6.9517i
```

Compute the multiplication of two random t-scalars  $A$  and  $B$ , both of them in the form of a  $2 \times 2 \times 3$  real array.

```
>> A = randn(2, 2, 3)
```

```
A(:, :, 1) =
```

```
-0.0068    -0.7697
1.5326     0.3714
```

```

```

MULTI-WAY FOURIER TRANSFORM AND INVERSE TRANSFORM. Liang Liao and Stephen John Maybank give a rigorous definition of multi-way Fourier transform and inverse transform in [LM20a, LM20b]. For convenience, the definition is organized as follows.

**Definition 2.2** (MULTI-WAY FOURIER TRANSFORM). The Fourier transform is a linear isomorphism defined by the  $N$ -mode multiplication of tensors, which sends each element  $X_T \in C \equiv \mathbb{C}^{I_1 \times \dots \times I_N}$  to  $\tilde{X}_T \in C \equiv \mathbb{C}^{I_1 \times \dots \times I_N}$  as follows.

$$\tilde{X}_T \doteq F(X_T) \doteq X_T \times_1 W_{mat}^{(I_1)} \cdots \times_k W_{mat}^{(I_n)} \cdots \times_N W_{mat}^{(I_N)} \in C \equiv \mathbb{C}^{I_1 \times \dots \times I_N} \quad (2.2)$$

where  $W_{mat}^{(I_n)} \in \mathbb{C}^{I_n \times I_n}$  denotes the  $I_n \times I_n$  Fourier matrix for all  $n \in [N]$ .

The  $(m_1, m_2)$ -th complex entry of the matrix  $W_{mat}^{(I_n)}$  is given by

$$\left( W_{mat}^{(I_n)} \right)_{m_1, m_2} = e^{2\pi i \cdot (m_1 - 1) \cdot (m_2 - 1) \cdot I_n^{-1}} \in \mathbb{C}, \quad \forall (m_1, m_2) \in [I_n] \times [I_n]. \quad (2.3)$$

The inverse multi-way transform  $F^{-1} : \tilde{X}_T \mapsto X_T$  is given by the following  $N$ -mode multiplication for tensors as follows.

$$X_T \doteq F^{-1}(\tilde{X}_T) = \tilde{X}_T \times_1 \left( W_{mat}^{(I_1)} \right)^{-1} \cdots \times_n \left( W_{mat}^{(I_n)} \right)^{-1} \cdots \times_N \left( W_{mat}^{(I_N)} \right)^{-1} \in C \equiv \mathbb{C}^{I_1 \times \dots \times I_N} \quad (2.4)$$

where  $\left( W_{mat}^{(I_n)} \right)^{-1}$  denotes the inverse of the matrix  $W_{mat}^{(I_n)}$  for all  $n \in [N]$ .

It is possible to employ a different multi-way transform and inverse transform to define a variant t-algebra  $C$ . Nevertheless, we only discuss the proposed algebra based on multi-way Fourier transforms or equivalently multi-way circular convolution. Interested readers are referred to [LM20a, LM20b] to connect the multi-way circular convolution and Fourier transform.

**2.2. FOURIER MATRIX:** `fourier_matrix`. Function `fourier_matrix` gives the  $n \times n$  Fourier matrix.

**FUNCTION 4. `fourier_matrix.m`:** function returns a  $n \times n$  Fourier transform

```
1 function fourier_matrix_result = fourier_matrix(n)
2 % this function computes the nxn Fourier matrix
3 assert(isscalar(n));
4 assert(n > 0);
5 fourier_matrix_result = fft(eye(n), [], 1);
6 end
```

#### SYNTAX

`Y = fourier_matrix(n)`

#### DESCRIPTION

Input `n` is a positive integer. Output `Y` is a  $n \times n$  complex matrix (i.e., Fourier matrix), whose  $(m_1, m_2)$ -th entry is given by equation (2.3).

#### EXAMPLES

The  $3 \times 3$  fourier matrix is as follows.

```
>> fourier_matrix(3)
ans =
    1.0000 + 0.0000i    1.0000 + 0.0000i    1.0000 + 0.0000i
    1.0000 + 0.0000i   -0.5000 - 0.8660i   -0.5000 + 0.8660i
    1.0000 + 0.0000i   -0.5000 + 0.8660i   -0.5000 - 0.8660i
```

The  $2 \times 2$  fourier matrix is as follows.

```
>> fourier_matrix(2)
ans =
     1     1
     1    -1
```

**Remark 2.3** (Shape of a Fourier matrix). A Fourier matrix must be square.

2.3. INVERSE FOURIER MATRIX: `ifourier_matrix`. The inverse Fourier transform is given by the following code.

FUNCTION 5. **ifourier\_matrix**: function returns a  $n \times n$  Fourier transform

```
1 function ifourier_matrix_result = ifourier_matrix(n)
2 % this function computes the nxn inverse Fourier matrix
3 ifourier_matrix_result = conj(fourier_matrix(n)) / n;
4 end
```

#### SYNTAX

`Y = ifourier_matrix(n)`

#### DESCRIPTION

Input  $n$  is a positive integer. Output  $Y$  is a  $n \times n$  complex matrix (i.e., inverse Fourier matrix). The output of `ifourier_matrix(n)` is the inverse matrix of the output of `fourier_matrix(n)`.

Let the  $n \times n$  Fourier matrix be  $X_{mat} \doteq W_{mat}^{(I_n)}$  and its inverse matrix be  $Y_{mat} \doteq (W_{mat}^{(I_n)})^{-1}$ . Besides the equality  $X_{mat} \cdot Y_{mat} = Y_{mat} \cdot X_{mat} = I_{mat}$ , the following equality holds

$$\begin{aligned} (Y_{mat})_{m_1, m_2} &= (1/n) \cdot \overline{(X_{mat})_{m_1, m_2}} \\ &= (1/n) \cdot e^{-2\pi i \cdot (m_1-1) \cdot (m_2-1) \cdot I_k^{-1}}, \quad \forall (m_1, m_2) \in [I_n] \times [I_n] \end{aligned} \quad (2.5)$$

Thus, FUNCTION 5 is an efficient way of computing an inverse Fourier matrix.

#### EXAMPLES

The  $3 \times 3$  inverse fourier matrix is given as follows.

```
>> ifourier_matrix(3)
ans =
    0.3333 + 0.0000i    0.3333 + 0.0000i    0.3333 + 0.0000i
    0.3333 + 0.0000i   -0.1667 + 0.2887i   -0.1667 - 0.2887i
    0.3333 + 0.0000i   -0.1667 - 0.2887i   -0.1667 + 0.2887i
```

2.4. **IDENTITY T-SCALAR:** `E_T`. The function returns the identity t-scalar of a given size is given as follows.

#### SYNTAX

```
E = E_T(tsize)
```

#### DESCRIPTION

Input `tsize` is a row array of positive integers. Output is an array whose inceptional entry is equal to 1, and the other entries are equal to 0. The identity t-scalar generalizes the canonical identity scalar 1.

#### EXAMPLES

The  $3 \times 3$  identity t-scalar is given as follows.

```
>> E_T([3, 3])
ans =
     1     0     0
     0     0     0
     0     0     0
```

Compute the multi-way Fourier transform of the  $3 \times 3$  identity t-scalar

```
>> fftn(E_T([3, 3]))
ans =
     1     1     1
     1     1     1
     1     1     1
```

The  $2 \times 3$  identity t-scalar  $E_T$  is given as follows.

```
>> E_T([2, 3])
ans =
     1     0     0
     0     0     0
```

Compute the multi-way Fourier transform of the  $2 \times 3$  identity t-scalar.

```
>> fftn(E_T([2, 3]))
ans =
     1     1     1
     1     1     1
```

2.5. **ZERO T-SCALAR:** `Z_T`. This function returns the zero t-scalar of a given size.

#### SYNTAX

```
Y = Z_T(tsize)
```

#### DESCRIPTION

Input `tsize` is a row array of positive integers. Output is an array of zeros. When `tsize` is a single positive integer, output is a square array of zeros.

#### EXAMPLES

The  $3 \times 3$  zero t-scalar is given as follows.

```
>> Z_T([3, 3])
ans =
     0     0     0
     0     0     0
     0     0     0
```

When the input argument is a single positive integer  $n$ , the output is a  $n \times n$  array of zeros.

```
>> Z_T(2)
ans =
     0     0
     0     0
```

The  $1 \times 3$  zero t-scalar is given as follows.

```
>> Z_T([1, 3])
ans =
     0     0     0
```

The  $2 \times 3 \times 2$  zero t-scalar is given as follows.

```
>> Z_T([2, 3, 2])
ans(:, :, 1) =
     0     0     0
     0     0     0
```

```
ans(:, :, 2) =
```

```
    0    0    0
    0    0    0
```

2.6. PSEUDO-INVERSE OF A T-SCALAR: `tpinv_tscalar`. This function returns the pseudo-inverse of a t-scalar.

#### SYNTAX

```
Y = tpinv_tscalar(tscalar)
```

#### DESCRIPTION

Input `tscalar` is a numeric array. Output `Y` is a numeric array of the same size. This function generalizes the reciprocal of non-zero complex number.

#### EXAMPLES

Compute the pseudo-inverse of a complex number.

```
>> tpinv_tscalar(5)
ans =
    0.2000

>> tpinv_tscalar(i)
ans =
    0.0000 - 1.0000i

>> tpinv_tscalar(0)
ans =
    0
```

The pseudo-inverse of the  $3 \times 3$  identity t-scalar  $E_T$  is itself.

```
>> tpinv_tscalar(E_T(3))
ans =
    1    0    0
    0    0    0
    0    0    0
```

The pseudo-inverse of the  $3 \times 3$  zero t-scalar  $Z_T$  is still  $Z_T$ .

```
>> tpinv_tscalar(Z_T(3))
ans =
    0    0    0
    0    0    0
```

0      0      0

Compute the pseudo-inverse of a random t-scalar.

```
>> X = randn([2, 3]) + i * randn([2, 3])
X =

-0.4336 + 0.7254i    3.5784 + 0.7147i    -1.3499 - 0.1241i
0.3426 - 0.0631i    2.7694 - 0.2050i    3.0349 + 1.4897i

>> tpinv_tscalar(X)
ans =

-0.0416 - 0.0168i    -0.0912 + 0.0271i    0.0751 - 0.0310i
-0.0027 - 0.0104i    0.0983 - 0.0268i    0.0764 + 0.0215i
```

Mathematically, the following equality holds

$$\begin{aligned} E_T^+ &\equiv E_T^{-1} \equiv E_T \\ Z_T^+ &\equiv Z_T \end{aligned} \quad (2.6)$$

where  $(\cdot)^+$  denotes the psuedo-inverse of a t-scalar, and  $(\cdot)^{-1}$  denotes the inverse of a t-scalar.

The zero t-scalar  $Z_T$  is non-invertible and the identity t-scalar  $E_T$  is invertible. Any t-scalar is pseudo-invertible [LM20a, LM20b].

**2.7. NORM AND ANGLE OF A T-SCALAR:** `tnorm_angle`. Function `tnorm_angle` returns the norm (i.e., generalized absolute value, a nonnegative t-scalar) and the generalized angle (a nonnegative t-scalar) of the t-scalar.

#### SYNTAX

```
[tnorm, tangle] = tnorm_angle(tscalar)
```

#### DESCRIPTION

Input `tscalar` and outputs `tnorm`, `tangle` are all numeric arrays of the same size.

#### EXAMPLES

```
>> tscalar = randn(3)
tscalar =

0.5377    0.8622    -0.4336
1.8339    0.3188    0.3426
-2.2588    -1.3077    3.5784
```

```
>> [tnorm, tangle] = tnorm_angle(tscalar)
tnorm =
    4.5066    -0.9511    -0.9511
   -0.5076    -0.0028     0.9449
   -0.5076     0.9449    -0.0028

tangle =
    0.0000 + 0.0000i    0.0000 + 0.0686i    0.0000 - 0.0686i
    0.0000 - 0.7277i    0.0000 + 0.4253i    0.0000 - 0.6812i
    0.0000 + 0.7277i    0.0000 + 0.6812i    0.0000 - 0.4253i
```

The multi-way Fourier transform of the norm of a t-scalar is an array of nonnegative real numbers. See the following example.

```
>> fftn(tnorm)
ans =
    3.4734    3.5006    3.5006
    2.1698    7.8579    5.0149
    2.1698    5.0149    7.8579
```

The multi-way Fourier transform of the angle of a t-scalar is an array of real numbers. See the following example.

```
>> fftn(tangle)
ans =
    0.0000 + 0.0000i    2.0351 - 0.0000i   -2.0351 - 0.0000i
   -1.7036 - 0.0000i   -1.8782 + 0.0000i   -0.1993 + 0.0000i
    1.7036 - 0.0000i    0.1993 + 0.0000i    1.8782 + 0.0000i
```

**2.8. CONJUGATE OF A T-SCALAR:** `tconj_tscalar`. Function `tconj_tscalar` returns the conjugate of a given t-scalar.

#### SYNTAX

```
conj_tscalar = tconj_tscalar(tscalar)
```

#### DESCRIPTION

Input `tscalar` and output `conj_tscalar` are numeric arrays of the same size.

#### EXAMPLES

```
>> X = randn(3, 2) + i * randn(3, 2)
X =
```

```

    0.0774 + 0.3714i   -0.0068 - 1.0891i
   -1.2141 - 0.2256i    1.5326 + 0.0326i
   -1.1135 + 1.1174i   -0.7697 + 0.5525i

>> Y = tconj_tscalar(X)
Y =
    0.0774 - 0.3714i   -0.0068 + 1.0891i
   -1.1135 - 1.1174i   -0.7697 - 0.5525i
   -1.2141 + 0.2256i    1.5326 - 0.0326i

>> [fftn(X), fftn(Y)]
ans =
    Columns 1 through 2

   -1.4941 + 0.7592i   -3.0064 + 1.7671i
   -0.7605 - 3.3628i    0.9168 + 3.3881i
    2.4662 + 0.4506i    2.3422 - 0.7739i

    Columns 3 through 4

   -1.4941 - 0.7592i   -3.0064 - 1.7671i
   -0.7605 + 3.3628i    0.9168 - 3.3881i
    2.4662 - 0.4506i    2.3422 + 0.7739i

```

**Remark 2.4.** From the above example, it shows  $\text{fftn}(X)$  is the conjugate array of  $\text{fftn}(Y)$ .

In the following example,  $A$  is a random  $t$ -scalar, and  $C$  is a so-called nonnegative  $t$ -scalar.

```

>> A = randn(3) + i * randn(3)
A =
   -0.8095 + 0.3192i    0.3252 - 0.0301i   -1.7115 + 1.0933i
   -2.9443 + 0.3129i   -0.7549 - 0.1649i   -0.1022 + 1.1093i
    1.4384 - 0.8649i    1.3703 + 0.6277i   -0.2414 - 0.8637i

>> C = tproduct(A, tconj_tscalar(A))
C =
   21.4860 - 0.0000i    4.5405 + 6.1719i    4.5405 - 6.1719i
   -4.4911 - 1.2003i    0.0077 + 2.2780i   -3.7334 + 3.5056i
   -4.4911 + 1.2003i   -3.7334 - 3.5056i    0.0077 - 2.2780i

```

```
>> fftn(C)
ans =
    14.1333 - 0.0000i    20.2526 + 0.0000i    3.1253 - 0.0000i
    46.7224 - 0.0000i    18.6277 - 0.0000i    6.3444 + 0.0000i
    30.8452 - 0.0000i    44.0261 - 0.0000i    9.2967 - 0.0000i
```

**Remark 2.5.** The above example shows the Fourier transform of a nonnegative t-scalar is an array of nonnegative real numbers.

2.9. **REAL PART OF A T-SCALAR:** `treal_part_tscalar`. For all t-scalar  $X_T \in C$ , the t-scalar in the form of  $\frac{X_T + X_T^*}{2}$  is called the real part of the t-scalar  $X_T$ .

It is easy to follow that the following equality holds for all  $X_T \in C$ ,

$$\left( \frac{X_T + X_T^*}{2} \right)^* \equiv \frac{X_T + X_T^*}{2} \quad (2.7)$$

The real part of a t-scalar is self-conjugate. Namely,  $\frac{X_T + X_T^*}{2} \in C^{sc}$ ,  $\forall X_T \in C$ , where  $C^{sc}$  denotes the subalgebra of  $C$  [LM20a, LM20b].

#### SYNTAX

```
real_part = treal_part_tscalar(tscalar)
```

#### DESCRIPTION

Input `tscalar` and output `real_part` are both numeric arrays of the same size, where `tscalar` can be any t-scalar in  $C$  and `real_part` is the so-called real part of `tscalar` and a self-conjugate t-scalar in  $C^{sc}$ .

#### EXAMPLES

```
>> A = randn(3)
A =
    1.1006    -1.4916     2.3505
    1.5442    -0.7423    -0.6156
    0.0859    -1.0616     0.7481

>> B = treal_part_tscalar(A)
B =
    1.1006     0.4294     0.4294
    0.8151     0.0029    -0.8386
    0.8151    -0.8386     0.0029

>> C = tconj_tscalar(B)
C =
```

```

1.1006    0.4294    0.4294
0.8151    0.0029   -0.8386
0.8151   -0.8386    0.0029

>> fftn(B)
ans =
1.9182    3.1371    3.1371
1.9800   -1.8240    0.7005
1.9800    0.7005   -1.8240

```

**Remark 2.6.** It follows from the above examples that  $C$  is identical to  $B$ , namely,  $B$  is self-conjugate. The Fourier transform of  $B$ , (i.e., a self-conjugate t-scalar) is an array of real numbers.

**2.10. IMAGINARY PART OF A T-SCALAR:** `timg_part_tscalar`. For all t-scalar  $X_T \in C$ , the t-scalar in the form of  $\frac{X_T - X_T^*}{2i}$  is called the imaginary part of the t-scalar  $X_T$ .

It is easy to follow that the following equality holds for all  $X_T \in C$ ,

$$\left( \frac{X_T - X_T^*}{2i} \right)^* \equiv \frac{X_T - X_T^*}{2i} \quad (2.8)$$

The imaginary part of a t-scalar is self-conjugate. Namely,  $\frac{X_T - X_T^*}{2i} \in C^{sc}$ ,  $\forall X_T \in C$ , where  $C^{sc}$  denotes the subalgebra of  $C$  [LM20a, LM20b].

#### SYNTAX

```
imag_part = timg_part_tscalar(tscalar)
```

#### DESCRIPTION

Input `tscalar` and output `imag_part` are both numeric arrays of the same size, where `tscalar` can be any t-scalar in  $C$  and `imag_part` is the so-called imaginary part of `tscalar` and a self-conjugate t-scalar in  $C^{sc}$ .

#### EXAMPLES

```

>> A = randn(3) + i * randn(3)
A =
0.2916 - 1.1480i   -0.8045 + 2.5855i   -0.2437 - 0.0825i
0.1978 + 0.1049i    0.6966 - 0.6669i    0.2157 - 1.9330i
1.5877 + 0.7223i    0.8351 + 0.1873i   -1.1658 - 0.4390i

>> B = timg_part_tscalar(A)
B =

```

```

-1.1480 + 0.0000i    1.2515 + 0.2804i    1.2515 - 0.2804i
 0.4136 + 0.6949i   -0.5529 - 0.9312i   -0.8728 + 0.3097i
 0.4136 - 0.6949i   -0.8728 - 0.3097i   -0.5529 + 0.9312i

>> C = tconj_tscalar(B)
C =
-1.1480 + 0.0000i    1.2515 + 0.2804i    1.2515 - 0.2804i
 0.4136 + 0.6949i   -0.5529 - 0.9312i   -0.8728 + 0.3097i
 0.4136 - 0.6949i   -0.8728 - 0.3097i   -0.5529 + 0.9312i

>> fftn(B)
ans =
-0.6694    -1.8103     1.5172
 2.4944    -0.7035    -2.8644
 2.2401    -3.2276    -7.3080

```

**Remark 2.7.** Since  $C$  is identical to  $B$ ,  $B$  is self-conjugate, and the Fourier transform of  $B$  (i.e., a self-conjugate  $t$ -scalar) is an array of real numbers.

2.11. **POWER OF A T-SCALAR:** `tpower`. Function `tpower` returns the  $p$  power of a  $t$ -scalar,  $Y_T = (X_T)^p$ . When  $p = \frac{1}{2}$ , the function returns the arithmetic square root of a  $t$ -scalar  $Y_T = \sqrt{X_T}$ .

#### SYNTAX

```
tscalar_power = tpower(tscalar, p_value)
```

#### DESCRIPTION

Input `tscalar` and outputs `tscalar_power` are numeric arrays of the same size. Input `p_value` is a canonical scalar, i.e., a complex number. Usually, input `p_value` is a real number.

#### EXAMPLES

```

>> A = randn(3) + i * randn(3)
A =
 1.7119 - 1.9609i   -0.8396 + 2.9080i    0.9610 - 1.0582i
-0.1941 - 0.1977i    1.3546 + 0.8252i    0.1240 - 0.4686i
-2.1384 - 1.2078i   -1.0722 + 1.3790i    1.4367 - 0.2725i

>> B = tpower(A, 2)
B =
 9.3472 + 4.9465i    5.5966 + 2.8883i   -16.1201 - 9.0661i
 6.2115 +10.0242i   18.5029 - 8.5377i   -16.8333 - 0.8297i
-10.9200 +16.9954i   14.1335 - 6.0189i    -8.1149 -10.5458i

```

```
>> fftn(A)
ans =

    1.3440 - 0.0535i    4.3826 - 2.3565i   -7.5884 - 7.6893i
    2.3033 - 2.7884i    3.8327 - 1.7446i    5.1228 - 4.2926i
    1.8525 + 2.5087i    7.0427 + 0.1217i   -2.8853 - 1.3535i
```

```
>> [fftn(A) .^2, fftn(B)]
ans =

    1.0e+02 *

Columns 1 through 3
    0.0180 - 0.0014i    0.1365 - 0.2066i   -0.0154 + 1.1670i
   -0.0247 - 0.1285i    0.1165 - 0.1337i    0.0782 - 0.4398i
   -0.0286 + 0.0929i    0.4959 + 0.0171i    0.0649 + 0.0781i
```

```
Columns 4 through 6
    0.0180 - 0.0014i    0.1365 - 0.2066i   -0.0154 + 1.1670i
   -0.0247 - 0.1285i    0.1165 - 0.1337i    0.0782 - 0.4398i
   -0.0286 + 0.0929i    0.4959 + 0.0171i    0.0649 + 0.0781i
```

**Remark 2.8.** The above example shows that the array  $\text{fftn}(A) \cdot^2$  is identical to the array  $\text{fftn}(B)$ .

More algebraically, for all t-scalar  $X_T \in C$ , let  $Y_T \doteq X_T^p$  and  $F(X_T) = \tilde{X}_T$  and  $F(Y_T) = \tilde{Y}_T$ . The following equality holds

$$\left( (\tilde{X}_T)_{m_1, m_2} \right)^p = (\tilde{Y}_T)_{m_1, m_2} \quad , \quad \forall m_1, m_2 . \quad (2.9)$$

When  $p = 1/2$ , one has the arithmetical square root of a t-scalar, which helps define the norm of a t-scalar or a t-matrix.

See the following examples.

```
>> C = tpower(A, 0.5)
C =

    1.7072 - 0.7392i   -0.5633 + 0.6266i    0.3416 + 0.1000i
    0.0274 - 0.0826i    0.2279 + 0.1667i    0.0453 - 0.0479i
   -0.2045 - 0.3783i   -0.5681 + 0.0536i    0.1459 + 0.2779i

>> [fftn(A) .^0.5, fftn(C)]
ans =

Columns 1 through 3
```

```

1.1595 - 0.0231i    2.1632 - 0.5447i    1.2678 - 3.0325i
1.7205 - 0.8104i    2.0055 - 0.4350i    2.4296 - 0.8834i
1.5766 + 0.7956i    2.6539 + 0.0229i    0.3884 - 1.7425i

```

Columns 4 through 6

```

1.1595 - 0.0231i    2.1632 - 0.5447i    1.2678 - 3.0325i
1.7205 - 0.8104i    2.0055 - 0.4350i    2.4296 - 0.8834i
1.5766 + 0.7956i    2.6539 + 0.0229i    0.3884 - 1.7425i

```

2.12. **RANDOM T-SCALAR:** `randn_tscalar`. For the convenience of demonstration, we give function `randn_tscalar`, which returns a random t-scalar.

#### SYNTAX

```
random_tscalar = randn_tscalar(tsize, mode)
```

#### DESCRIPTION

Input `tsize` is a row numeric array. Input `mode` is either `'real'` or `'complex'`. If only one input `tsize` is given, the second input is set to the default value `'complex'`.

#### EXAMPLES

```

>> randn_tscalar([2, 3])
ans =
    1.0984 - 1.5771i    0.7015 + 0.2820i   -0.3538 - 1.3337i
   -0.2779 + 0.5080i   -2.0518 + 0.0335i   -0.8236 + 1.1275i

>> randn_tscalar(3, 'real')
ans =
   -0.7145   -0.5890   -1.1201
    1.3514   -0.2938    2.5260
   -0.2248   -0.8479    1.6555

```

The following examples show that, for all t-scalar  $X_T \in C$ , the following equality holds [LM20a, LM20b]

$$X_T \circ X_T^* \equiv \operatorname{Re}(X_T)^2 + \operatorname{Im}(X_T)^2 \in S^{\operatorname{nonneg}} \quad (2.10)$$

```

>> X = randn_tscalar(2)
X =
    0.3075 + 0.7914i   -0.8655 - 2.3299i
   -1.2571 - 1.3320i   -0.1765 - 1.4491i

>> [tproduct(X, tconj_tscalar(X)); ...

```

```
tpower(treal_part_tscalar(X), 2) + ...
tpower(timg_part_tscalar(X), 2)]
```

```
ans =
  12.3839 + 0.0000i    0.0841 + 0.0000i
   4.1764 - 0.0000i    5.9805 - 0.0000i
  12.3839 + 0.0000i    0.0841 + 0.0000i
   4.1764 + 0.0000i    5.9805 + 0.0000i
```

The following example shows that, for all  $X_T \in C$ , the t-scalar  $X_T \circ X_T^*$  is nonnegative. In other words,  $F(X_T \circ X_T^*)$  returns an array of nonnegative real numbers.

```
>> fftn(tproduct(X, tconj_tscalar(X)))
```

```
ans =
  22.6249 + 0.0000i   10.4956 - 0.0000i
   2.3111 + 0.0000i   14.1038 + 0.0000i
```

2.13. GENERALIZED EXPONENTIAL: `texp`. Generalized exponential of a t-scalar.

#### SYNTAX

```
exp_result = texp(tscalar)
```

#### DESCRIPTION

Input `tscalar` and output `exp_result` are numeric arrays of the same size.

#### EXAMPLES

Calculate the exponential of 1, which is Euler's number,  $e$ .

```
>> texp(1)
ans =
  2.7183
```

Calculate the exponential of 0, which is equal to 1.

```
>> texp(0)
ans =
  1
```

Calculate the exponential of  $i$ , which is equal to  $e^i \equiv \cos 1 + i \sin 1$ .

```
>> texp(i)
ans =
  0.5403 + 0.8415i
```

Calculate the exponential of  $E_T$  of the size  $3 \times 3$ , i.e.  $e^{E_T} = e \cdot E_T$ , which generalizes Euler's number  $e$ .

```
>> texp(E_T(3))
ans =
    2.7183         0         0
         0         0         0
         0         0         0
```

Calculate the exponential of  $Z_T$  of the size  $3 \times 3$ , i.e.  $e^{Z_T} = E_T$ , which generalizes the canonical scalar 1.

```
>> texp(Z_T(3))
ans =
    1         0         0
    0         0         0
    0         0         0
```

Calculate the exponential of a random t-scalar of the size  $2 \times 3$ .

```
>> X = randn_tscalar([2, 3])
X =
    0.3335 + 0.8620i    0.4517 + 0.4550i    0.1837 - 0.3349i
    0.3914 - 1.3617i   -0.1303 - 0.8487i   -0.4762 + 0.5528i

>> texp(X)
ans =
    0.2069 + 0.4511i   -0.6209 - 0.7939i   -0.1891 + 0.4643i

```

**Remark 2.9** (Expotential of a t-scalar). For all  $X_T \in C$ , the expotential of  $X_T$  is a t-scalar given by the following series

$$e^{X_T} \doteq \sum_{k=1}^{+\infty} \frac{X_T^{(k-1)}}{k-1} = E_T + X_T + \frac{X_T^2}{2} + \frac{X_T^3}{6} + \frac{X_T^4}{24} + \cdots \in C . \quad (2.11)$$

For all  $X_T \in C$ , let  $F(X_T) = \tilde{X}_T$  and  $F(e^{X_T}) = \tilde{Y}_T$ . By the semisimplicity of  $C$  introduced in [LM20a], the following equality holds in the following domain

$$e^\alpha = \beta \in \mathbb{C} \quad (2.12)$$

where  $\alpha \doteq (\tilde{X}_T)_{m_1, m_2} \in \mathbb{C}$  and  $\beta \doteq (\tilde{Y}_T)_{m_1, m_2}$  for all  $m_1, m_2$ .

**2.14. NATURAL LOGARITHM OF A T-SCALAR:** `tlog`. Function `tlog` generalizes the natural logarithm of a canonical scalar and is the inverse function of function `texp`.

Function `tlog` is the MATLAB implementation of the map  $\ln : X_T \mapsto \ln X_T \in C$ .

The following equalities hold

$$\begin{aligned} \ln X_T &= \sum_{k=1}^{+\infty} \frac{2}{2k-1} \left( \frac{X_T - E_T}{X_T + E_T} \right)^{2k-1}, \quad \forall X_T \in S^{nonneg} \\ \ln X_T &= \sum_{k=1}^{+\infty} (-1)^{k+1} \frac{(X_T - E_T)^k}{k}, \quad \forall X_T \text{ satisfying } |X_T - E_T| \leq E_T. \end{aligned} \quad (2.13)$$

where  $|\cdot| \in S^{nonneg}$  denotes the norm of a t-scalar.

#### SYNTAX

```
log_result = tlog(tscalar)
```

#### DESCRIPTION

Input `tscalar` and output `log_result` are also numeric arrays of the same size.

#### EXAMPLES

Calculate the natural logarithm of 1, which is equal to 0.

```
>> tlog(1)
ans =
    0
```

Calculate the natural logarithm of  $e$ , which is equal to 1.

```
>> tlog(exp(1))
ans =
    1
```

Compute the natural logarithm of the  $3 \times 3$  identity t-scalar  $E_T$ , which is the  $3 \times 3$  zero t-scalar  $Z_T$ .

```
>> tlog(E_T(3))
ans =
    0    0    0
    0    0    0
    0    0    0
```

Function `tlog` is the inverse function of `texp`.

```
>> X = randn_tscalar(3)
X =
    0.5377 + 2.7694i    0.8622 + 0.7254i   -0.4336 - 0.2050i
    1.8339 - 1.3499i    0.3188 - 0.0631i    0.3426 - 0.1241i
```

```

-2.2588 + 3.0349i  -1.3077 + 0.7147i   3.5784 + 1.4897i

>> Y = tlog(texp(X))
Y =
    0.5377 - 0.0231i    0.8622 + 0.0273i   -0.4336 - 0.9031i
   -0.5845 - 2.0480i    1.5280 - 0.7612i   -0.2620 + 0.2249i
    0.1596 + 2.3368i   -0.7031 + 1.0638i    2.3692 + 0.7916i

```

**2.15. ABSOLUTE VALUE OF A T-SCALAR:** `tabs_tscalar`. Function `tabs_tscalar` returns the absolute value of a t-scalar and is an efficient implementation of function `tnorm_angle` returning only the first output.

#### SYNTAX

```
Y = tabs_tscalar(X)
```

#### DESCRIPTION

Function `tabs_tscalar` returns the norm (i.e., generalized absolute value, a non-negative t-scalar) of a t-scalar. It generalizes the absolute value of a complex number.

#### EXAMPLES

Compute the absolute value of  $3 + 4i$ , which is equal to 5.

```

>> tabs_tscalar(3 + 4*i)
ans =
    5

```

Compute the absolute value of  $1 + i$ , which is equal to  $\sqrt{2}$ .

```

>> tabs_tscalar(1 + i)
ans =
    1.4142

```

Compute the absolute value of  $3 \cdot E_T + 4i \cdot E_T$ , which is equal to  $5 \cdot E_T$ .

```

>> tabs_tscalar(3 * E_T(3) + 4 * i * E_T(3))
ans =
    5     0     0
    0     0     0
    0     0     0

```

Compute the absolute value of  $(1 + i) \cdot E_T$ , which is equal to  $\sqrt{2} \cdot E_T$ .

```

>> tabs_tscalar((1 + i) * E_T(3))
ans =

```

1.4142	0	0
0	0	0
0	0	0

Compute the absolute value of a random t-scalar, which is a nonnegative t-scalar.

```
>> X = randn_tscalar(3)
X =
    1.4090 - 0.3034i   -1.2075 + 0.8884i    0.4889 - 0.8095i
    1.4172 + 0.2939i    0.7172 - 1.1471i    1.0347 - 2.9443i
    0.6715 - 0.7873i    1.6302 - 1.0689i    0.7269 + 1.4384i

>> Y = tabs_tscalar(X)
Y =
    4.4986 + 0.0000i    0.3981 + 0.7577i    0.3981 - 0.7577i
   -0.1722 + 0.3195i    0.2519 + 0.3154i    1.3705 + 0.3892i
   -0.1722 - 0.3195i    1.3705 - 0.3892i    0.2519 - 0.3154i

>> fftn(Y)
ans =
    8.1951    3.3182    0.9491
    5.6186    8.0814    1.9729
    2.0707    4.8391    5.4425
```

**2.16. ANGLE OF A T-SCALAR:** `tangle_tscalar`. Function `tabs_tscalar` returns the absolute value of a t-scalar and is an efficient implementation of function `tnorm_angle` returning only the second output.

#### SYNTAX

```
tangle = tangle_tscalar(tscalar)
```

#### DESCRIPTION

Input `tscalar` and outputs `tangle` are also numeric arrays of the same size. Function `tangle_tscalar` returns a nonnegative t-scalar which generalizes the phrase angle of a complex number.

**EXAMPLES** Compute the phrase angle of complex number  $1 + i$ , which is equal to  $\frac{\pi}{4}$ .

```
>> tangle_tscalar(1 + i)
ans =
    0.7854
```

The phrase angle of the t-scalar  $(1 + i) \cdot E_T$  is equal to  $\frac{\pi}{4} \cdot E_T$ .

```
>> tangle_tscalar((1 + i) * E_T(3))
ans =
    0.7854         0         0
         0         0         0
         0         0         0
```

Compute the phrase angle of a random t-scalar in  $C$ , which is a self-conjugate in  $C^{cs}$ .

```
>> X = randn_tscalar(3)
X =
    0.3252 - 0.0301i   -1.7115 + 1.0933i    0.3192 + 0.0774i
   -0.7549 - 0.1649i   -0.1022 + 1.1093i    0.3129 - 1.2141i
    1.3703 + 0.6277i   -0.2414 - 0.8637i   -0.8649 - 1.1135i

>> Y = tangle_tscalar(X)
Y =
    0.2518 + 0.0000i    0.0937 + 0.2899i    0.0937 - 0.2899i
   -0.9435 + 0.4960i   -0.2052 - 0.1029i   -0.4711 - 0.6768i
   -0.9435 - 0.4960i   -0.4711 + 0.6768i   -0.2052 + 0.1029i

>> fftn(Y)
ans =
   -2.8003    0.4435   -2.5487
    1.5677    1.9041    2.6915
    2.5503   -0.3668   -1.1751
```

**2.17. WHETHER INPUT IS A SELF-CONJUGATE:** `is_self_conjugate`. This function determines whether input is a self-conjugate t-scalar.

#### SYNTAX

```
bool_result = is_self_conjugate(tscalar)
```

#### DESCRIPTION

Input `tscalar` is a numeric array and output `bool_result` is boolean, and `true` if `tscalar` is self-conjugate, otherwise, `false`.

#### EXAMPLES

The number 1 is self-conjugate.

```
>> is_self_conjugate(1)
ans =
    logical
         1
```

Any real number is self-conjugate.

```
>> is_self_conjugate(0.5)
ans =
    logical
     1
```

```
>> is_self_conjugate(pi)
ans =
    logical
     1
```

Any element in  $\mathbb{C} \setminus \mathbb{R}$  is not self-conjugate

```
>> is_self_conjugate(i)
ans =
    logical
     0
```

```
>> is_self_conjugate(1 + i)
ans =
    logical
     0
```

A random t-scalar is not self-conjugate.

```
>> is_self_conjugate(randn_tscalar(3))
ans =
    logical
     0
```

The real part of a random t-scalar is self-conjugate.

```
>> is_self_conjugate(treal_part_tscalar(randn_tscalar(3)) )
ans =
    logical
     1
```

The imaginary part of a random t-scalar is self-conjugate.

```
>> is_self_conjugate(timg_part_tscalar(randn_tscalar(3)) )
ans =
    logical
     1
```

The absolute value of a random t-scalar is self-conjugate.

```
>> is_self_conjugate(tabs_tscalar(randn_tscalar(3)) )
ans =
    logical
     1
```

**2.18. WHETHER INPUT IS A NONNEGATIVE:** `is_nonnegative`. This function determines whether input is a nonnegative t-scalar.

**SYNTAX**

```
bool_result = is_nonnegative(tscalar)
```

**DESCRIPTION**

The input `tscalar` is a numeric array and the output `bool_result` is boolean, and true if `tscalar` is a nonnegative t-scalar, otherwise, false.

**EXAMPLES**

```
>> is_nonnegative(1)
ans =
    logical
     1

>> is_nonnegative(0)
ans =
    logical
     1

>> is_nonnegative(-1)
ans =
    logical
     0

>> is_nonnegative(E_T([2, 3, 4]))
ans =
    logical
     1

>> is_nonnegative(Z_T([3, 5, 7, 9]))
ans =
    logical
     1
```

The t-scalar  $X_T = -1 \cdot E_T$  is not nonnegative, but self-conjugate

```
>> is_nonnegative(-1 * E_T([5, 11, 23]))
ans =
    logical
     0
```

```
>> is_self_conjugate(-1 * E_T([5, 11, 23]))
ans =
    logical
     1
```

The absolute value of any t-scalar is nonnegative.

```
>> is_nonnegative(tabs_tscalar(randn_tscalar([3, 4, 5, 9])) )
ans =
    logical
     1
```

**2.19. INFINUM OF A SET OF TWO SELF-CONJUGATE T-SCALARS: `tinfn`.** This function returns the infimum of a set of two self-conjugate t-scalars.

#### SYNTAX

```
infimum_tscalar = tinfn(tscalar1, tscalar2)
```

#### DESCRIPTION

Inputs `tscalar1` and `tscalar2` and output `infimum_tscalar` are numeric arrays of the same size. Function `tinfn` generalizes  $\min(\alpha, \beta)$  of two real numbers  $\alpha$  and  $\beta$ .

#### EXAMPLES

The infimum of  $\{-1, 3\}$  is  $-1$ .

```
>> tinfn(-1, 3)
ans =
    -1
```

The infimum of  $\{Z_T, E_T\}$  is  $Z_T$ .

```
>> tinfn(Z_T(3), E_T(3))
ans =
     0     0     0
     0     0     0
     0     0     0
```

Compute the infimum of a set of two random self-conjugate t-scalars.

```
>> X = treal_part_tscalar(randn_tscalar(3))
X =
-0.3523 + 0.0000i  -0.2677 - 0.5828i  -0.2677 + 0.5828i
 1.4030 - 0.9531i   0.6374 + 0.8028i  -0.4042 + 0.4081i
 1.4030 + 0.9531i  -0.4042 - 0.4081i   0.6374 - 0.8028i

>> Y = treal_part_tscalar(randn_tscalar(3))
Y =
-1.5246 + 0.0000i  -0.4078 + 0.8015i  -0.4078 - 0.8015i
 0.4044 + 0.7344i   0.9958 - 0.0609i   0.1535 + 0.1239i
 0.4044 - 0.7344i   0.1535 - 0.1239i   0.9958 + 0.0609i

>> tinf(X, Y)
ans =
-2.4893 + 0.0000i   0.0746 + 0.1859i   0.0746 - 0.1859i
 0.8868 - 0.1011i   1.2877 + 0.6646i  -0.6208 + 0.2339i
 0.8868 + 0.1011i  -0.6208 - 0.2339i   1.2877 - 0.6646i

>> fftn(X)
ans =
 2.3847   2.1624   2.8137
-2.0774  -6.9840  -1.1567
-2.9705   1.5397   1.1174

>> fftn(Y)
ans =

-5.2749   0.6478  -4.9756
```

## 3. FUNCTIONS FOR T-MATRICES

**3.1. MULTIPLICATION OF TWO T-MATRICES:** `tmultiplication`. This function generalizes the canonical multiplication of two complex matrices.

Let  $C$  be the set of all  $I_1 \times \cdots \times I_N$  complex arrays, namely  $C \equiv \mathbb{C}^{I_1 \times \cdots \times I_N}$ . For all t-matrices  $A_{TM} \in C^{M_1 \times M} \equiv \mathbb{C}^{I_1 \times \cdots \times I_N \times M_1 \times M}$ , and  $B_{TM} \in C^{D \times D_2} \equiv \mathbb{C}^{I_1 \times \cdots \times I_N \times M \times M_2}$ , their t-matrix multiplication  $C_{TM} \doteq A_{TM} \circ B_{TM}$  is an element in  $C^{M_1 \times M_2} \equiv \mathbb{C}^{I_1 \times \cdots \times I_N \times M_1 \times M_2}$  defined as follows.

**Definition 3.1** (T-matrix multiplication). The  $(m_1, m_2)$ -th t-scalar entry  $(C_{TM})_{m_1, m_2} \in C \equiv \mathbb{C}^{I_1 \times \cdots \times I_N}$  of  $C_{TM}$  is given by

$$(C_{TM})_{m_1, m_2} \doteq \sum_{m=1}^M (A_{TM})_{m_1, m} \circ (B_{TM})_{m, m_2} \quad , \quad \forall (m_1, m_2) \in [M_1] \times [M_2] \quad . \quad (3.1)$$

where  $(A_{TM})_{m_1, m} \circ (A_{TM})_{m, m_2}$  denotes the t-scalar product (i.e.,  $N$ -way circular convolution) of two  $I_1 \times \cdots \times I_N$  complex arrays (see Definition 2.1).

**SYNTAX**

```
tmatrix_result = tmultiplication(tmatrix1, tmatrix2, tsize)
```

**DESCRIPTION**

Inputs `tmatrix1` and `tmatrix2` are numeric arrays, and input `tsize` is a row array of positive integers, representing the size  $I_1 \times \cdots \times I_N$ . Output `tmatrix_result` is a numeric array.

This function generalizes the multiplication of two complex matrices.

**EXAMPLES**

Compute the multiplication of two (canonical) complex matrices A and B, where A is a  $5 \times 3$  complex matrix and B is a  $3 \times 2$  complex matrix.

```
>> A = randn(5, 3) + i * randn(5, 3)
A =
-0.8095 + 1.0933i    1.3703 - 1.1135i    0.3129 - 0.2256i
-2.9443 + 1.1093i   -1.7115 - 0.0068i   -0.8649 + 1.1174i
 1.4384 - 0.8637i   -0.1022 + 1.5326i   -0.0301 - 1.0891i
 0.3252 + 0.0774i   -0.2414 - 0.7697i   -0.1649 + 0.0326i
-0.7549 - 1.2141i    0.3192 + 0.3714i    0.6277 + 0.5525i

>> B = randn(3, 2) + i * randn(3, 2)
B =
 1.1006 + 2.3505i   -1.4916 - 0.1924i
 1.5442 - 0.6156i   -0.7423 + 0.8886i
 0.0859 + 0.7481i   -1.0616 - 0.7648i
```

```
>> A * B
ans =
-1.8344 - 3.0478i    0.8854 + 0.5695i
-9.4052 - 5.2075i    7.6544 - 3.1285i
 5.2108 + 4.7439i   -4.3987 + 0.9620i
-0.7091 - 0.3109i    0.5929 + 0.2704i
 2.3850 - 2.2167i    0.0817 + 0.8975i

>> squeeze(tmultiplication(reshape(A, [1, 5, 3]), ...
reshape(B, [1, 3, 2]), 1))
ans =
-1.8344 - 3.0478i    0.8854 + 0.5695i
-9.4052 - 5.2075i    7.6544 - 3.1285i
 5.2108 + 4.7439i   -4.3987 + 0.9620i
-0.7091 - 0.3109i    0.5929 + 0.2704i
 2.3850 - 2.2167i    0.0817 + 0.8975i
```

Compute t-matrix multiplication when A is a  $3 \times 3 \times 5 \times 7$  real array, B is a  $3 \times 3 \times 7 \times 11$  real array, and tsize is equal to  $[3, 3]$ . The result t-matrix C is a  $3 \times 3 \times 5 \times 11$  real array.

```
>> A = randn([3, 3, 5, 7]); B = randn([3, 3, 7, 11]); ...
C = tmultiplication(A, B, [3, 3]); whos;
Name          Size          Bytes  Class      Attributes

A              3x3x5x7             2520  double
B              3x3x7x11            5544  double
C              3x3x5x11            3960  double

>> tsize = [5, 7]; ...
row_num1 = 11; col_num1 = 13; row_num2 = 13; col_num2 = 17; ...
A = randn([tsize, row_num1, col_num1]) + ...
    i * randn([tsize, row_num1, col_num1]); ....
B = randn([tsize, row_num2, col_num2]) + ...
    i * randn([tsize, row_num2, col_num2]); ...
C = tmultiplication(A, B, tsize); ...
whos A; whos B; whos C;
```

Name	Size	Bytes	Class	Attributes
A	5x7x11x13	80080	double	complex

  

Name	Size	Bytes	Class	Attributes
------	------	-------	-------	------------

B	5x7x13x17	123760	double	complex
Name	Size	Bytes	Class	Attributes
C	5x7x11x17	104720	double	complex

**3.2. RANK OF A T-MATRIX: `trank`.** This function computes the rank, a nonnegative t-scalar, of a t-matrix and generalizes the rank of a complex matrix.

#### SYNTAX

```
generalized_rank = trank(tmatrix, tsize)
```

#### DESCRIPTION

Input `tmatrix` is a numeric array. input `tsize` is a row array of positive integers, representing the size  $I_1 \times \cdots \times I_N$ .

Output `generalized_rank` is a  $I_1 \times \cdots \times I_N$  numerical array, namely, a nonnegative t-scalar.

#### EXAMPLES

Compute the rank of a random  $3 \times 3$  t-scalar.

```
>> A = randn_tscalar([2, 3])
A =
    0.5377 - 0.4336i   -2.2588 + 3.5784i    0.3188 - 1.3499i
    1.8339 + 0.3426i    0.8622 + 2.7694i   -1.3077 + 3.0349i

>> trank(A, [2, 3])
ans =
     1     0     0
     0     0     0
```

Compute the rank of a random rank-deficient t-scalar.

```
>> B = randn(3) + i * randn(3); B(3) = 0; B = ifftn(B)
B =
   -0.1815 - 0.1793i    0.1117 - 0.5259i   -0.0164 + 0.1007i
    0.1309 - 0.8840i    0.2987 - 0.1716i    0.0873 + 0.1710i
    0.1853 + 0.5892i   -0.1343 - 0.2487i    0.4068 - 0.5628i

>> trank(B, [3, 3])
ans =
    0.8889 + 0.0000i   -0.1111 + 0.0000i   -0.1111 + 0.0000i
    0.0556 + 0.0962i    0.0556 + 0.0962i    0.0556 + 0.0962i
    0.0556 - 0.0962i    0.0556 - 0.0962i    0.0556 - 0.0962i
```

```
>> fftn(trank(B, [3, 3]))
ans =
    1.0000    1.0000    1.0000
    1.0000    1.0000    1.0000
         0    1.0000    1.0000
```

Compute the rank a random  $2 \times 5$  t-matrix with  $3 \times 3$  t-scalar entries. The maximum rank a  $2 \times 5$  t-matrix is  $2 \cdot E_T$ .

```
>> A = randn(3, 3, 2, 5) + i * randn(3, 3, 2, 5);
>> trank(A, [3, 3])
ans =
     2     0     0
     0     0     0
     0     0     0
```

Compute the rank a random  $2 \times 5$  t-matrix with  $3 \times 3$  t-scalar entries and the first row t-vectors are set to zero.

```
>> B = randn(3, 3, 2, 5) + i * randn(3, 3, 2, 5); ...
B(:, :, 1, :) = 0;
>> trank(B, [3, 3])
ans =
     1     0     0
     0     0     0
     0     0     0
```

**3.3. IDENTITY T-MATRIX: teye.** This function returns the identity t-matrix of a given size.

#### SYNTAX

```
t_identity_matrix = teye(row_col_num, tsize)
```

#### DESCRIPTION

Input `row_col_num` is a nonnegative t-scalar. Input `tsize` is row array of positive integers, representing  $I_1 \times \cdots \times I_N$ . Output `t_identity_matrix` is a numeric array, a diagonal t-matrix. This function generalizes the identity matrix.

#### EXAMPLES

Compute the  $2 \times 2$  identity t-matrix, whose t-scalar entries are  $3 \times 3$  numerical arrays.

```
>> A = teye(2, [3, 3])
A(:, :, 1, 1) =
```

$$\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{array}$$

$$\begin{array}{l} A(:, :, 2, 1) = \\ \begin{array}{ccc} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{array} \end{array}$$

$$\begin{array}{l} A(:, :, 1, 2) = \\ \begin{array}{ccc} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{array} \end{array}$$

$$\begin{array}{l} A(:, :, 2, 2) = \\ \begin{array}{ccc} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{array} \end{array}$$

3.4. CONJUGATE TRANSPOSE A T-MATRIX: `tctranspose`. This function computes the conjugate transpose of a t-matrix and generalizes the conjugate transpose of a complex matrix.

#### SYNTAX

```
tmatrix_result = tctranspose(tmatrix, tsize)
```

#### DESCRIPTION

Input `tmatrix` is a  $I_1 \times \cdots \times I_N \times M_1 \times M_2$  numeric array, and input `tsize` is row array of positive integers, representing  $I_1 \times \cdots \times I_N$ .

Output `tmatrix_result` is a  $I_1 \times \cdots \times I_N \times M_2 \times M_1$  numeric array.

Given a  $M_1 \times M_2$  t-matrix  $A_{TM} \in C^{M_1 \times M_2} \equiv \mathbb{C}^{I_1 \times \cdots \times I_N \times M_1 \times M_2}$ , function `tctranspose` returns a  $M_2 \times M_1$  t-matrix  $A_{TM}^* \in C^{M_1 \times M_2} \equiv \mathbb{C}^{I_1 \times \cdots \times M_2 \times M_1}$  such that the following condition holds

$$(A_{TM})_{m_1, m_2}^* = (A_{TM}^*)_{m_2, m_1} \in \mathbb{C}^{I_1 \times \cdots \times I_N}, \quad \forall (m_1, m_2) \in [M_1] \times [M_2]. \quad (3.2)$$

#### EXAMPLES

Compute the conjugate transpose of a  $5 \times 7$  t-matrix, whose t-sclalar entries are  $3 \times 3$  arrays.

```
>> A = randn(3, 3, 5, 7) + i * randn(3, 3, 5, 7); ...
B = tctranspose(A, [3, 3]);
>> whos
  Name      Size      Bytes  Class      Attributes
  A         3x3x5x7      5040  double     complex
  B         3x3x7x5      5040  double     complex

>> norm(A(:, :, 1, 3) - tconj_tscalar(B(:, :, 3, 1)), 'F')
ans =
    1.1233e-15
```

**3.5. INVERSE OF A T-MATRIX: `tin`.** This function computes the inverse of a t-matrix and generalizes the inverse of a complex matrix.

#### SYNTAX

```
tresult = tin(tmatrix, tsize)
```

#### DESCRIPTION

Input `tmatrix` is numeric arrays, and input `tsize` is row array of positive integers, representing  $I_1 \times \cdots \times I_N$ . Output `tresult` is a numeric array, i.e., a nonnegative t-scalar.

If the t-matrix `tmatrix` is non-invertible, output `tresult` is a NaN.

#### EXAMPLES

Compute a zero t-matrix.

```
>> tsize = [3, 3]; row_num = 5; col_num = 5;
>> A = zeros([tsize, row_num, col_num]);
>> tin(A, tsize)
ans =
    NaN
```

Given a full-rank square t-matrix  $A_T \in C^{M \times M} \equiv \mathbb{C}^{I_1 \times \cdots \times I_N \times M \times M}$ , let the inverse t-matrix of  $A_T$  be  $B_T \doteq A_T^{-1} \in C^{M \times M} \equiv \mathbb{C}^{I_1 \times \cdots \times I_N \times M \times M}$ . Then,

$$A_T \circ B_T = B_T \circ A_T = \underbrace{\text{diag}(E_T, \cdots, E_T)}_{M \text{ copies}} \quad (3.3)$$

Compute the inverse of a random t-matrix.

```
>> tsize = [3, 3]; row_num = 5; col_num = 5;
>> A = randn([tsize, row_num, col_num]);
>> B = tinv(A, tsize);
>> norm(reshape(tmultiplication(A, B, tsize) ...
- teye(row_num, tsize), 1, []))
ans =
    9.5911e-15
```

Given a t-matrix, if its row number and column number is equal to 1, function `tinv` compute the rank a t-scalar.

```
>> tsize = [3, 3];
>> A = randn(tsize);
>> B = tinv(A, tsize);
>> tproduct(A, B)
ans =
    1.0000    0.0000    0.0000
    0.0000   -0.0000    0.0000
    0.0000    0.0000   -0.0000
```

The above example can be rewritten as follows.

```
>> tsize = [3, 3]; row_num = 1; col_num = 1;
>> A = randn([tsize, row_num, col_num]);
>> B = tinv(A, tsize);
>> tmultiplication(A, B, tsize)
ans =
    1.0000   -0.0000    0.0000
    0.0000    0.0000    0.0000
   -0.0000   -0.0000   -0.0000
```

**3.6. PSEUDO-INVERSE OF A T-MATRIX: `tpinv`.** This function computes the pseudo-inverse of a t-matrix and generalizes the function `tinv`.

#### SYNTAX

```
tresult = tpinv(tmatrix, tsize)
```

#### DESCRIPTION

Input `tmatrix` is a numeric array, and input `tsize` is row array of positive integers, representing  $I_1 \times \cdots \times I_N$ . Output `tmatrix_result` is a numeric array.

This function generalizes the inverse of a complex matrix.

#### EXAMPLES

Compute the pseudo-inverse of canonical complex matrix.

```
>> tsize = 1; row_num = 2; col_num = 3; ...
A = randn(row_num, col_num) + i * randn(row_num, col_num)
A =
    0.8998 - 0.2130i    1.0294 - 1.0431i    1.0128 - 0.4381i
   -0.3001 - 0.8657i   -0.3451 - 0.2701i    0.6293 - 0.4087i

>> B = tpinv(reshape(A, [tsize, row_num, col_num]), tsize);
>> B = reshape(B, col_num, row_num)
B =
    0.0627 - 0.1945i   -0.4116 + 0.5594i
    0.3892 + 0.2522i   -0.1208 - 0.3298i
    0.1468 + 0.3941i    0.7343 - 0.0552i

>> A * B
ans =
    1.0000 + 0.0000i    0.0000 - 0.0000i
   -0.0000 - 0.0000i    1.0000 + 0.0000i
```

Compute the pseudo-inverse of a random t-matrix.

```
>> tsize = [3, 3]; row_num = 2; col_num = 3;
>> A = randn([tsize, row_num, col_num]) ...
+ i * randn([tsize, row_num, col_num])
A(:, :, 1, 1) =

**3.7. COMPACT TENSORIAL SINGULAR VECTOR DECOMPOSITION OF A T-MATRIX:** `tsvd`. This function computes the compact SVD (Tensorial Singular Vector Decomposition) of a t-matrix. This function generalizes the SVD of complex matrix.

#### SYNTAX

```
[TU, TS, TV] = tsvd(tmatrix, tsize)
```

#### DESCRIPTION

Input `tmatrix` is a numeric array, and input `tsize` is row array of positive integers, representing  $I_1 \times \cdots \times I_N$ . Outputs `TU`, `TS`, `TV` are all numeric arrays, i.e., three t-matrices.

Given a t-matrix  $X_{TM} \in C^{M_1 \times M_2} \equiv \mathbb{C}^{I_1 \times \cdots \times I_N \times M_1 \times M_2}$ , let  $D \doteq \min(M_1, M_2)$ . Then, the TSVD decompose the t-matrix  $X_{TM}$  to three t-matrices

$$\begin{aligned} U_{TM} &\in C^{M_1 \times D} \equiv \mathbb{C}^{I_1 \times \cdots \times I_N \times M_1 \times D} \\ V_{TM} &\in C^{M_2 \times D} \equiv \mathbb{C}^{I_1 \times \cdots \times I_N \times M_2 \times D} \\ S_{TM} &\doteq \text{diag}(\lambda_{T,1}, \dots, \lambda_{T,D}) \in C^{D \times D} \equiv \mathbb{C}^{I_1 \times \cdots \times I_N \times D \times D} \end{aligned} \quad (3.4)$$

where  $\lambda_{T,d} \in S^{\text{nonneg}}$  for all  $d \in [D]$ , and  $\lambda_{T,d} \geq \lambda_{T,(d+1)}$  for all  $d \in [D-1]$ .

The binary relation  $\geq$  is the partial order generalizing the usual total order  $\geq$  of nonnegative real numbers.

Given two nonnegative  $A_T, B_T \in S^{\text{nonneg}}$ ,  $A_T \geq B_T$  if and only if  $(A_T - B_T) \in S^{\text{nonneg}}$ . Otherwise,  $A_T$  and  $B_T$  are incomparable.

The following t-matrix multiplication hold

$$X_{TM} = U_{TM} \circ S_{TM} \circ V_{TM}^* \quad (3.5)$$

where  $V_{TM}^*$  denotes the conjugate transpose (hermitian tranpose) of the t-matrix  $V_{TM}$  [LM20a, LM20b].

#### EXAMPLES

##### FUNCTION 6. Example: TSV of a random t-matrix

```
1 function tsvd_demo
2 % The following code demonstrate the TSVD of a random t-matrix
3 clear; close all; clc;
4
5 % The shape of t-scalars is set to $3*3*3$
6 tsize = [3, 3];
```

```

7  M1 = 5;
8  M2 = 3;
9
10 t_matrix = randn([tsize, M1, M2]);
11 [U, S, V] = tsvd(t_matrix, tsize);
12 whos t_matrix;
13 whos U;
14 whos S;
15 whos V;
16
17 tmatrix_product_result = tmultiplication(U, S, tsize);
18 tmatrix_product_result = tmultiplication(tmatrix_product_result,
    tctranspose(V, tsize), tsize);
19 whos tmatrix_product_result;
20
21 residual = norm(tmatrix_product_result(:) - t_matrix(:));
22 fprintf('residual = %f \n', residual);
23 end

```

The result of the above script is as follows.

Name	Size	Bytes	Class	Attributes
t_matrix	3x3x5x3	1080	double	

Name	Size	Bytes	Class	Attributes
U	3x3x5x3	1080	double	

Name	Size	Bytes	Class	Attributes
S	3x3x3x3	648	double	

Name	Size	Bytes	Class	Attributes
V	3x3x3x3	648	double	

Name	Size	Bytes	Class	Attributes
tmatrix_product_result	3x3x5x3	1080	double	

```
residual = 0.000000
```
